transfer provides an exciting new approach for the treatment of retinal and choroidal diseases. Two areas of concern are the potential for toxicity and uncertainties associated with prolonged vector-related transgene expression. One way to address these concerns for transfer of genes encoding secreted proteins is to transduce cells on the outside of the eye, provided the gene product can gain access to the eye and have the desired effect. In this study, we investigated the feasibility of this approach. Periocular injection of an adenoviral vector encoding beta-galactosidase (AdLacZ.10) resulted in LacZ-stained cells throughout the orbit and around the eye. Compared to periocular injection of $5 \times 10(9)$ particles of control vector, periocular injection of 5 \times 10(9) or 1 \times 10(9) particles of an adenoviral vector expressing pigment epithelium-derived factor (PEDF) regulated by a CMV promoter (AdPEDF.11) resulted in significantly elevated intraocular levels of PEDF and suppression of choroidal neovascularization. Periocularly injected recombinant PEDF was also found to diffuse through the sclera into the eye. Although similar experiments are needed in an animal with a human-sized eye, these data suggest that periocular gene transfer deserves consideration for the diseases.Gene Therapy (2003) 10, 637-646. treatment of choroidal doi:10.1038/sj.qt.3301931

delivery to the intraocular tissues of the retina is ABSTRACT: Gene hampered by complicated surgical interventions to administer the gene. Here we showed that instillation as eye drops of an expression plasmid vector for beta-galactosidase gene carried by the specific kinds of liposomes could transfer the gene to the retinal ganglion cells of rat, without causing any inflammation. This non-surgical, convenient way for delivery to the retina would facilitate the development of treatment for various intraocular diseases.

6-carboxyfluorescein (6-FAM)-labeled PURPOSE: After inducing phosphorothicate oligonucleotides (S-ODNs) noninvasively into albino rabbit eyes by iontophoresis, we assessed the transfer of S-ODNs into the ocular tissues, their stability, and the possible presence of injury to the ocular tissues. METHODS: The iontophoresis group consisted of 12 eyes of 6 rabbits and the control group consisted of 4 eyes of 2 rabbits given eye drops containing S-ODNs. Aqueous humor and vitreous humor were collected after subjected to electrophoresis with a fluorescent DNA iontophoresis, sequencer and analyzed by the Gene Scan program. Frozen sections at 10 microns were prepared for observations under a fluorescent microscope. A plasmid 4.7 kbp in size that expresses green fluorescent protein (GFP) was induced into 18 eyes of 9 rabbits by the same procedure. RESULTS: In the iontophoresis group, S-ODNs were detected in the anterior chamber 5 minutes after electrophoresis and in the vitreous 10 minutes after. These S-ODNs maintained the same length as at the initial synthesis. S-ODNs could also be detected in the posterior retina 20 minutes after electrophoresis. No evidence of degeneration or inflammation due to the above procedure was found in the ocular tissues. Fluorescence showing GFP gene expressions were in the cornea, the anterior chamber angle, and the ciliary found subepithelial tissues. CONCLUSIONS: These findings show that iontophoresis is an effective method to induce gene into rabbit eyes.
